
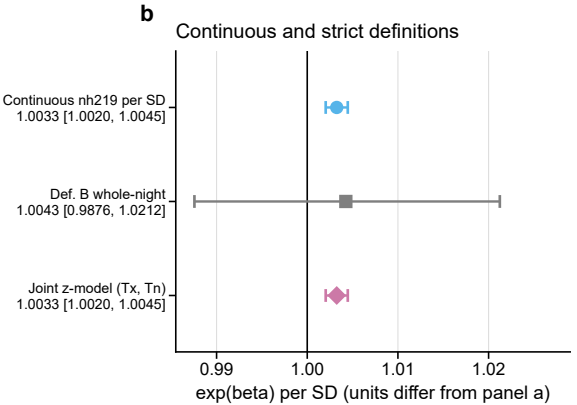
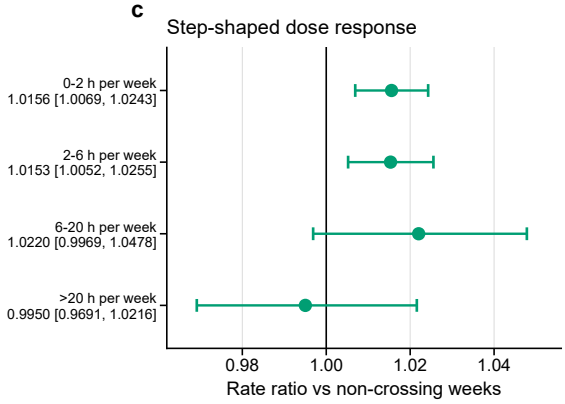
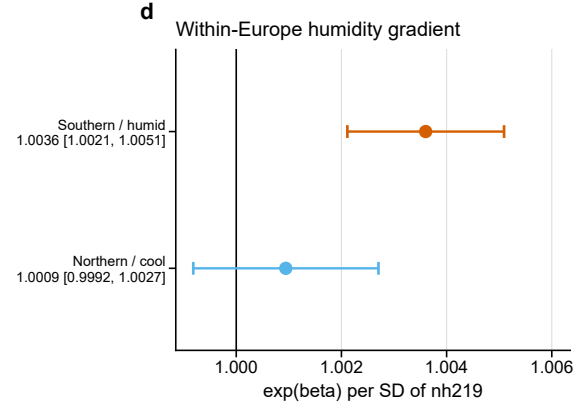
n = 136 regions (133 with the TX>=30 control). Heterogeneity I2 = 78.2% from the JSON; an earlier print showed 1% because of a formatting bug.



Def. B is estimable in only 30 of 135 regions: low power, not a null result. Per-SD units are not comparable with panel a.



64 contributing regions. The top bin does not separate from unity: risk attaches to crossing, not to additional hours.



South minus north contrast: dbeta = +0.0027, z = +2.26, p = 0.024. The gradient is present only where the exposure has variance.
